

## IMPROVED SUPERHEATED VAPOR GENERATOR SYSTEM AND METHOD

Applicant hereby claims the benefit under 35 USC 119(e) of the following United States provisional patent application, No. 60/200423 filed on April 28, 2000.

### FIELD OF THE INVENTION

The invention pertains to superheated vapor generators and systems for delivering superheated vapor flows as well as methods of fabrication and use of such superheated vapor generators and systems for providing desired flows of superheated vapor including substantially continuous flows.

### DESCRIPTION OF THE PRIOR ART

Prior patents include U.S. Pat No. 6,006,009 (the '009 Patent), U.S. Pat. No. 5,471,556 (the '556 Patent) and U.S. Pat No. 4,414,037 (the '037 Patent) owned by the inventor and applicant herein, co-pending U.S. Pat. application Ser. No. 08/484,019 owned by the applicant and inventor herein for Superheated Vapor Generator and Control System and Method, all incorporated by reference herein, references cited in connection with aforesaid U.S. Pat. No. 4,414,037 including U.S. Pat. Nos. 2,505,656; 2,753,212; 2,861,838; 2,983,450; 3,039,454; 3,218,741; 3,718,805 and 3,721,802. and patents cited in connection with said U.S. Pat. No. 5,471,556 including U.S. Pat. Nos. 377,228; 2,652,645; 3,436,852; 3,119,004; 3,869,815; 4,255,646; 3,508,354; 3,823,497; and 2,576,976.

The aforesaid references in the main refer to apparatus and methods for generating steam from liquid drawn from a reservoir.

The '037 Patent discloses apparatus for generating superheated steam or other vapor from liquid drawn from a self-contained reservoir and includes means in the form of a nozzle for directing superheated steam or other vapor to desired locations. The '556 Patent discloses improvements relative to the '037 Patent. Said co-pending application discloses further improvements.

Equipment disclosed in the aforesaid patents and co-pending application is employable for effecting, among other things, cleaning and/or sterilization. This apparatus has proved highly useful for such purposes. In operation, such equipment provides flows of superheated vapor upon activation of a control member. Duration and frequency of such flows have been limited by the recovery time of the vapor generator. This is the time required for the temperature of the vapor generator to recover to the operating level after vaporization into superheated vapor of liquid entering the vaporization chamber. As prescribed by the laws of thermodynamics, the transfer of heat to the liquid in the process of vaporization causes a decrease in temperature of the vaporization chamber walls to the point where generation of superheated vapor ceases. Methods and devices described and claimed in the '009 patent address this issue by providing a plurality of vapor generators connected and controlled to provide sequential outputs of superheated vapor.

In virtually all applications, whether involving single vapor generators or a plurality of outputting units, decrease in recovery time for individual vapor generator units would promote efficiency, economy and usability. In addition, increased power/pressure (i.e., psi) of the emitted superheated vapor steam would be advantageous as providing greater range and improved effectiveness at any and all ranges.

Therefore, there has been a felt but unfulfilled need for devices and methods providing superheated vapor generators having decreased recovery time as well as increased output pressure.

#### SUMMARY OF THE INVENTION

An improved superheated vapor generator defines an internal vaporizing chamber having augmented inner-wall surface comprising at least one thermal element in the vaporization chamber. Means for delivering superheated vapor flow include a control member connectable to the vapor generator having means to direct the flow of superheated vapor and means for controlling intake of liquid to the vapor generator.

A method for fabricating a superheated vapor generator in accordance with the invention includes the steps of providing at least two sections secureable together to define an enclosed interior space, and providing at least one thermal element for inclusion in said interior space, and further including the step of fastening said at least two sections together such that said at least one thermal element is in the interior space defined thereby or alternatively is capable of being placed therein. The wall portion of the vaporization chamber may have any desired arbitrary surface

configuration and in particular embodiments may be substantially smooth, etched, grooved, or including perforations of arbitrary cross-section or irregularities such as crack-like openings among other configurations in accordance with the invention.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 is a perspective view of a system in accordance with the invention;

FIG. 2 is a section through the line 2-2 of FIG. 1;

FIG. 3 is a section of a vapor generator member in accordance with the invention taken along the line 3-3 of FIG. 4;

FIG. 4 is a sectional view taken along the line 4-4 of FIG. 1;

FIG. 5 is a sectional view taken along the line 5-5 of FIG. 4;

FIG. 6 is a sectional view, somewhat simplified, of a further particular embodiment of a vaporization chamber in accordance with the invention;

FIG. 7 is a sectional view, somewhat simplified, of another particular embodiment of a vaporization chamber in accordance with the invention;

FIG. 8 is a sectional view, somewhat simplified, of still another particular embodiment of a vaporization chamber in accordance with the invention;

FIG. 9 is a sectional view, somewhat simplified, of yet another particular embodiment of a vaporization chamber in accordance with the invention; and

FIG. 10 including FIGS. 10a-10e is a schematic diagram of a method in accordance with the invention.

### **DETAILED DESCRIPTION OF THE INVENTION**

Referring to FIGS. 1-5, inclusive, a superheated vapor generation and control system 10 includes a base 12 forming the bottom of a housing 14. The housing 14 together with base 12 functions as a container for system 10. The top and sides of housing 14 are fastened to base 12 by conventional means and are removable to permit access to the interior of system 10. Details of particular aspects of system 10 are fully disclosed and described in the '556 patent incorporated by reference herein; thus, common features will be described in summary fashion herein.

Controls of system 10 are disposed upon a portion of housing 14 comprising a control panel 16 and a power switch 18, controlling drawing of power from an external source, i.e., whether the system 10 is "On" or "Off".

Disposed upon control panel 16 are a removable line fuse holder 20 and a white power light 22, to indicate power in system 10. Also disposed on control panel 16 is a manual vapor heating switch 24 for controlling the generation of steam and/or superheated vapor. An amber vapor generator light 26 is disposed on control panel 16 as an indicator of the operation of thermostatic regulation of a vapor generator.

A footswitch receptacle 28 is disposed in panel 16 and accommodates a foot switch (not shown) for controlling superheated vapor production. A power line 30 is accommodated in a fitting 32 attached to panel 16 around a slot 34 for passage therethrough of power line 30.

An amber heating chamber light 36 is positioned on panel 16 adjacent power light 22 and is electrically connected as described in the '556 Patent to remain on while current is being drawn for heating. A liquid pick-up tube inlet 38 is defined in control panel 16 to receive a liquid pick-up tube 40.

At the top of housing 14 is disposed a carrying handle 42 secured by fasteners 44 to housing 14. In a rear panel 46 of housing 14, an aperture 48 is defined; secured on both sides of aperture 48 is a gasket-type fitting 50. Aperture 48 and gasket 50 accommodate and receive a vapor exit pipe connector 52. A quick disconnect connector member 54 is disposed at an outer end of pipe 52 and is connectable to a vapor control member or wand 56. Wand 56 contains a grip handle 58 in which is disposed a vapor control switch 59 operable by a vapor control push button 60. A tube 62 extends outwardly from control member handle 58. A vapor control power connector 64 connects between vapor control 60 and into a socket 64 and is mounted in rear panel 46. A support plate 66 is fastened to base 12, which in turn rests upon feet 68.

A mounting plate 70 is fastened to support 66. Fastened to mounting plate 70 is a pump 72, which includes a cylinder 74 receiving a piston 76 reciprocating within cylinder 74. Piston 74 is pivotably connected to a rod 78 which with a pivoting member 80 at the opposite end of the rod forms pivotable connection between the rod 78 and piston 76. A substantially square cam 82 is pivotably attached to pivot member 80 and pivots and is rotatable on a shaft 84 mounted and pivotably journaled in plate 70.

An electric motor 86 is mounted upon mounting plate 70 and rotates shaft 84. Electric motor 86 is wired to withstand heat generated in system 10. Cam 82 is rotated by shaft 84, which in turn rotates on a sleeve in pivot member 80. An inlet fitting 88 accommodates inflow of liquid from inlet port 38 through inlet conduit 40. A first check valve 90 is connected to inlet fitting 88. Check valve 90 not only blocks backflow and prevents intake of solids into the apparatus but also affects the liquid content of superheated vapor produced by system 10.

A fitting 92 is connected to check valve 90 and accommodates flow of liquid therethrough to a T-fitting 94. T-fitting 94 is connected to the fluid intake inlet 88. Connected to T-fitting 94 is a second check valve 100 which in turn is connected to fitting 96. Check valve 100 is identical to check valve 90.

From fitting 96 fluid passes through a fitting 104 which is connectable to a tube 106, depicted as coiled for economy of space utilization. Tube 106 leads into a superheated vapor generator 120. A sleeve 107 is secured to tube 106 at its point of entry into generator 120. Sleeve 107 is preferably composed of aluminum and is welded to tube 106. Sleeve 107 preferably extends above the top surface of generator 120 and is secured to generator 120 at an exterior weld 109 and an interior weld 111.

A male connector 110 is fastened to a screw 112 mounted in panel 16 and connected to vapor switch 24. A bracket 114 fastened to plate 12 provides support and mounting for vapor generator 108.

Electric gear motor 86 is secured by a fastener 115 to mounting bracket 70. Electric gear motor 86 is of conventional type and drives pump 72 by means of cam 82 journaled on shaft 84 which in turn is driven by motor 86. A pair of buffer members 113 upon motor 106 are in contact with bracket 70 for the purpose of minimizing the effect of vibration upon the structure.

Vapor generator 120 comprises metal castings in two parts welded together at 122 defining a vaporization chamber 126. Generator 120 is detachably positioned within housing 14 and is secured thereto at bracket 114 as noted hereinabove, and rests on washers 124 between plate 66 and bracket 114. The bottom section of vapor generator 120 is longer to allow room for a heating element 132 described in full in the '556 Patent. As depicted, chamber 126 is substantially spherical; however, other configurations may be employed in accordance with the invention. In the depicted configuration, the periphery of chamber 126 is referred to on occasion as a wall 125. In other configurations in accordance with the invention such periphery may comprise more than one wall.

The peripheral interior surface of wall 125 of chamber 126 is cut in a plurality of ridges and grooves 127, 127' respectively. The depth of the grooves 127' and the height of the ridges 127 are irregular, with the height and depth in a preferred embodiment varying substantially randomly between 0.0030-0.0050 inch. The ridges and grooves 127 are in the form of substantially concentric circles about an axis of generator 120.

In addition, cross-grain ridges and grooves are defined in wall 125 of chamber 126 and denoted by numerals 128, 128', respectively. Cross-grain ridges and grooves 128, 128' are, like the ridges and grooves 127, 127' of random and irregular dimensions. Ridges and grooves 128, 128' in the preferred embodiment vary randomly between 0.0020-0.0050 inch. It has been found that the groove and ridge configuration together with the irregularities in the depth of the grooves and the height of the ridges provides improved efficiency of vapor generation as, for example, more rapid vaporization with comparable or smaller energy consumption.

Disposed within chamber 126 are a plurality of thermal elements 129a, 129b. In the particular embodiment depicted and described, thermal elements 129a, 129b are shown as two in number, for purpose of specificity. In accordance with the invention the number of thermal elements may range from one (1) to whatever number may be desired. Thermal elements 129a, 129b may be but need not be in contact with surface 125. Thermal elements 129a, 129b may be but need not be attached to wall 125.

Thermal elements 129a, 129b may be of arbitrary shape and size and are depicted as generally cylindrical and tubular for sake of particularity. Elements 129a, 129b are composed of thermally conductive material.

Preferably, thermal elements 129a, 129b are composed of the same material as wall 125 of the interior of chamber 126. In this manner, electrolysis between thermal elements 129a, 129b on the one hand and interior surface of wall 125 on the other hand, is avoided.

To the extent that dissimilar metals can be mated without electrolysis such metals may be employed with advantage as, for example, stainless steel for surface 125 and aluminum for thermal elements 129a, 129b, and vice versa.

In accordance with the invention, the shape and surface of the interior surface of wall 125 of chamber 126 may be selected as appropriate for particular applications.

Defined in generator 120 is a receptacle 130 for receiving and accommodating a heating element cartridge 132. Alternatively, heating elements may be cast-in upon fabrication of the generator 120. Heating cartridge 132 is affixed in receptacle 130 by means of cement of conventional type which is resistant to high temperatures. Receptacle 130 is open at both ends, traversing the length of generator 120. At a receiving end, receptacle 130 defines an aperture 134 which is dimensioned to receive cartridge 132. At its opposite end, receptacle 130 opens to an aperture 136 that is preferably smaller than aperture 134. Aperture 136 is dimensioned to accommodate a pin or tamping member (not shown) for thrusting through receptacle 130 to the base of cartridge 132 thereby ejecting cartridge 132 when desired. Thus, a spent or broken cartridge can be removed for repair or replacement in an economical, cost efficient, and expeditious manner.

Heating cartridge 132 is of generally cylindrical configuration. Cartridge 132 defines an included volume 138 which contains a coil of resistance wire 140. An outer sheath 142 of heating cartridge 132 is fabricated of high temperature alloy of conventional type. One end of heating cartridge 132 is closed by end plate 144; adjoining the opposite end of heating cartridge 132 is a terminal block 146. Terminal block 146

comprises a bracket for supporting a pair of leads 150, 152. Leads, 150, 152 are enclosed in temperature insulation sheaths 154, 156, respectively. Sheaths 154, 156 may be of standard material such as high temperature fiberglass for the purpose of protecting against the elevated temperatures produced by heating cartridge 132. Heating cartridge 132 has a seal 158 substantially flush with the end of cartridge 142 and comprising thermally insulated material such as epoxy or cement.

The entire generator 120 is sheathed in insulated material such as fiberglass (not shown). The heat generated is such that the entire generator normally heats to 500°F. and above, creating an oven-like effect surrounding the chamber 126 and its contents. A first thermostat 160 is positioned in thermal contact with generator 120; thermostat 160 is preferably set to turn off at approximately 500°F., plus or minus ten percent (10%). Electrical terminals 164 accommodate wires (not shown) connecting to the electrical system of system 10 so as to turn off the power to the heating element 132 when the desired temperature is reached. Preferably thermostat 160 is flush mounted to the generator 120 as, for example, by screwing the thermostat into a slot together with conventional means (not shown) to prevent slippage of thermostat 160.

A second thermostat 166 is depicted as positioned approximately 90° along the circumference of generator 120 from first thermostat 160. Other positions, of course, may be employed in accordance with the invention. Second thermostat 166 is mounted in generator 120 and has a pair of electrical terminals 168 connectable to the electrical system of the apparatus. As fully described hereinbelow, second thermostat 166 is set to cut off current to the heating cartridge 132 in the event of failure of first thermostat 160 such that the temperature of the chamber 126 shall not exceed 550°F.

The electrical circuitry for control of system 10 is depicted and described in detail in the '556 Patent. Power switch 18 controls the on/off condition of the entire system. Switch 24 is a manual vapor generator switch which as noted above is mounted on control panel 16. Wand switch 192 is actuated by push button 60 and like switch 24 controls vapor generation but is contained in the wand 56 for ease of operation of the device. Switches 24, 192 control the on/off condition of pump motor 72. A terminal block 202 is fastened to base plate 12 and contains terminals 204 which provide electrical connections for the electrical circuitry of system 10.

A spark suppressor 206 is depicted as being connected with first thermostat 160 and second thermostat 166. The purpose of spark suppressor 206 is to prevent the respective thermostats from arcing. In the event that the spark suppressor 206 and the first thermostat 160 should fail, creating the danger of overheating and destruction of the unit, the second thermostat 166 at 550°F. will cut off. A thermofuse 207 cuts in upon failure of the second thermostat 166 and, will break the generator circuit at 650°F.

Red light 26 is connected to be on when the first thermostat 160 has cut out while the second thermostat 166 continues to operate, thus notifying the operator of a change in condition in the system.

White light 22 is illuminated when power switch 18 is closed (i.e., when the power switch is turned on). The amber light 36 is on when heating element 132 is drawing current. Light 36 remains on so long as heating element 132 draws current. When light 36 goes out, this indicates that generator 120 has reached its operating

temperature. A foot jack switch control 208 is connected to and mounted upon foot switch receptacle 28 on panel 16 and performs the same function as switches 24, 192. Removable power line fuse 20 is depicted as in series with power switch 18. A relay arrangement may be employed to supply current to the heating element immediately upon actuation of any of the vapor control switches so as to maintain, in conjunction with the thermostats, a substantially constant power supply and temperature for vapor generation.

Heating cartridge 132 preferably delivers substantially 1000 watts of power to maintain temperature of the vapor generator 120 at 500 °F. Other power delivery rates and operating temperatures, higher and lower, may be employed in accordance with the invention. The motor RPM is substantially equal to 366 and the pump delivery rate is preferably 4.9 gallons per hour. Other motor RPM and pump delivery rates may be employed in accordance with the invention.

As depicted in FIG. 6, a vaporization chamber 240 is generally spherical in form and has an interior wall 241 having a generally smooth interior surface 242. Thermal elements 244a, 244b are disposed in chamber 240 in the same manner as described in connection with the embodiment depicted in Figs. 1-5, inclusive.

As depicted in FIG. 7, a vaporization chamber 250 is generally spherical in form and has an interior wall 251 whose interior surface 252 defines a plurality of etches 253, which are as described and depicted in the aforesaid '037 Patent. Thermal elements 254a, 254b are disposed in chamber 250 in the same manner as described in connection with the embodiment depicted in FIGS. 1-5, inclusive.

As depicted in FIG. 8, a vaporization chamber 260 is substantially spherical in form having an interior wall 261 which has an interior surface 262 defining a plurality of perforations 263 of surface 262 comprising arbitrary and irregular cross-sections as described in the aforesaid pending patent application. Thermal elements 264a, 264b are disposed in chamber 260 in the same manner as described above.

Depicted in FIG. 9 is a vaporization chamber 270 substantially spherical in form having an interior wall 271 having an interior surface 272 which defines a plurality of arbitrary, irregular openings through surface 272, including elongated openings in the nature of crevices or cracks 273. Thermal elements 274a, 274b are disposed in chamber 270 in the same manner as described above.

Vapor control member or wand 56 comprises a conduit member 57, a handle member 58, and a tube 62 as discussed hereinabove. Detailed description and depiction of wand 56 and associated structures are contained in the '556 Patent hereby incorporated by reference herein.

In operation, system 10 is connected by hose 40 to source of liquid (not shown). The liquid may be any of a broad range related to the purposes for which the system 10 is to be used. In a typical cleaning context in which the system is employed to loosen and dissolve dirt as on machinery or circuit boards or in corners of a room, 100% undiluted water, distilled or deionized, may be employed. Additives such as detergents or disinfectants may be employed provided that they are stable at the operating temperatures of the system. The proportions of additives and water may be varied

depending on the application. The solution may contain vaporizers, emulsifiers, degreasers, oxidants, alkalis, deodorizers, antiseptics, germicides, or the like. In addition, the liquid may comprise humidifiers, fresheners, and other reagents which the user may wish to impart to the air or to a surface or object.

Particular applications of the system include cleaning of equipment, circuit boards and/or surfaces and spaces such as rooms in connection with maintenance or janitorial work. Wand 56 provides the capability for precise direction of the vapor flow even to small objectives and in particular allows impingement of the vapor into small, confined, or relatively inaccessible objects or spaces. Apparatus in accordance with the invention provides a general purpose cleaning capability with particular applicability to remote or relatively inaccessible areas, objects and small parts.

The invention may be employed in connection with burnishing or cleaning of small parts such as time-piece apparatus, in connection with metal plating, printing and photo-engraving, lapidary and stone cutting activity, manufacture and/or repair of electronic components, removal of such things as wallpaper, labels and the like, in connection with dry-cleaning, sanitizing and sterilizing of eating implements, in connection with optical and optometric laboratory and office work, with jewelry, dental and medical offices and operating theatres, miniature instrument manufacture and repair, and biological and analytic laboratories, among many other applications. Use of apparatus in accordance with the invention is particularly advantageous in that its flexibility permits cleaning of parts to be accomplished with a minimum of disassembly, degreasing and decontamination whereby cleaning is made environmentally compatible.

A particularly useful application of the invention is in connection with the cleaning and maintenance of military equipment, including weapons and related items. This has become timely in view of the current emphasis on repair and maintenance as opposed to acquisition of new items.

The operator directs the tube 62 toward the object to receive superheated vapor, which issues from tube 62. The superheated vapor such as steam, is "dry", i.e., having a high proportion of gas as opposed to content of fluid droplets. This has a favorable effect in that the amount of liquid included in the vapor is so small that the residue does not interfere with further cleaning and does not require a cleanup, the amount of fluid residue being so small that it can normally be readily removed by a cloth or paper towel. Pooling of liquid is virtually eliminated. The material removed by a towel in the form of a residue is easily disposed of, particularly in cases where any removed contaminants are non-hazardous or non-toxic.

By use of the invention, the operator gains the capability of precisely directing relatively dry vapor to the object targeted. The operator can control the amount of heat transferred to any target by varying the distance between the end of the tube 62 and the object of the heat, decreasing the distance and increasing the heat applied, increasing the distance and decreasing the heat applied. The invention produces a jet of superheated vapor of a temperature of approximately 500° F. at the nozzle.

Superheated vapor issues at relatively high pressure, approximately 120-200 and higher psi for single vaporization units and to at least 300 + psi for multiple

vaporization generator systems as disclosed and claimed in the '009 Patent. As a result of this pressure range, the superheated vapor impinges upon, and into such relatively hard-to-reach spaces as portholes, crevices, and the like such pressure range being greater than available with prior devices.

Recovery times of superheated vapor generators in accordance with the invention are decreased in contrast to those available with prior devices.

Relatively more rapid recovery of vaporization chambers in accordance with the invention enables employment of smaller chambers and fewer chambers (when used in a multi-chamber arrangement as depicted and described in the '009 Patent) which is useful in connection with applications requiring large and/or substantially continuous outputs of superheated vapor.

In addition, increased output pressure of superheated vapor from wand 56 results in longer and higher-volume output streams. Application of heat causes contaminants to soften, liquefy, and generally decompose or disengage from the surfaces on which they are disposed. This applies to such normally hard-to-clean substances as grease, oil, grime, paste, glue, and carbon. For removal of tenacious contaminants, heat applied by the invention initiates cleaning. Then a cleaner or emulsifier may be applied in conventional fashion at which point a further flow of superheated vapor from the invention completes removal of the contaminant.

Other applications for the invention are, among others, lubrication, particularly of relatively inaccessible and small parts. Lubrication applied in this manner is a most

effective type of hot lubrication in that the surface having been first cleaned by use of the invention in a cleaning mode, the lubricant can be applied by disposing lubricant on the now clean, heated parts by conventional means and then subjecting the parts to a flow of superheated vapor, causing the lubricant to be dispersed evenly throughout and upon the object to be lubricated.

The vapor output pressure increase due to use of improved generators including interior thermal elements affords greater flexibility and effectiveness for system 10. Output superheated vapor may be employed in a longer stream than previously feasible or with greater contact effectiveness at previous stream lengths, or a combination of these, as well as providing the capability of producing streams having greater widths and the like, much as in the variable stream patterns available with conventional garden hoses and nozzles.

A method for fabricating superheated vapor generators in accordance with the invention is depicted in FIG. 10. Two separate, preferably semi-cylindrical, parts are provided. One part may have a longer axial extent than the other for purposes of accommodating a heating cartridge -- or a cast-in heating element -- and providing sufficient heat dissipative area to prevent undue heat and temperature build-up. The parts have hollow sections comprising the vaporization chamber.

As shown in FIG. 10a the hollow interior section of the parts may be either cast or machined to define a series of ridges and grooves of randomly varying heights and depths in a manner such that they are concentric or helical about the longitudinal axis of the part.

As shown in FIG. 10a radial grooves are then machined or cast in the parts, such grooves also having varying depths and heights. The radial grooves may be 10-12 in number, and other quantities may be utilized as well in accordance with the invention. Full details of this procedure are specified in the '556 Patent.

The parts are then welded together and may be fastened within a housing of a system in accordance with the invention.

At least one thermal element may be disposed within the assembled chamber by placement therein prior to securing the parts together; alternatively, thermal elements may be placed within the assembled chamber by insertion thereto through openings defined therein for passage thereinto of conduits for fluid and vapor flow.

Depicted in FIG. 10b is a method of fabrication of superheated vapor generators having etched walls as in the '037 Patent.

Etches in the wall of sections of a vaporization chamber are produced as disclosed in the '037 patent. Thereafter, at least one thermal element is disposed in the sections which are secured together. As in the method of FIG 10a, at least one thermal element may be inserted within the completed chamber through a conduit/opening.

In FIG. 10c, a method is depicted for fabricating a vaporization chamber having substantially smooth inner walls having at least one thermal element therein. The method of FIG. 10c is the same as those described in connection with FIGS. 10a, 10b

hereinabove differing only in the characteristic of the inner surfaces of the vaporization chamber walls.

Depicted in FIG. 10d, is a method for fabricating a vaporization chamber having walls with perforations in the surface thereof as provided in the aforesaid pending application. At least one thermal element is disposed in the vaporization chamber as described in connection with FIGS. 10a-10c above.

Depicted in FIG. 10e is a method of fabricating a vaporization chamber having an interior wall surface with irregularities including penetrations through the interior surface in the nature of cracks/crevices. The separate sections of the vaporization chamber are chemically or physically treated or cast from a mold/pattern having these configurations as part of the mold/pattern and processed by conventional methods to provide an interior surface with cracks/crevices. Thermal elements are disposed in the vaporization chamber as stated above.

There have therefore been provided an improved vapor generator and control system. Though a preferred embodiment has been described and depicted herein, the scope of the invention is defined by the claims to be filed pursuant to law and interpreted in light of the specification and drawings.
